INTRODUCTION

This pamphlet is the first in a series of reports describing the geology and water resources of Hughes County. It is designed to be an uncomplicated, non-technical aid in the search for sand and gravel deposits.

Other reports in the series include:

The first report describes the availability, quality, and location of major aquifers (water-bearing deposits) in a short, easy to read pamphlet. The second report describes a more technical and somewhat more exhaustive investigation of the water resources of the County. The third report describes a scientific investigation of the geology of Hughes County.

GEOLOGIC OVERVIEW

Most of the sand and gravel deposits found in Hughes County were deposited by glacial ice or melt-water streams which covered the region thousands of years ago. Others have been deposited by streams since the retreat of the glaciers. A short description of geologic terms used in this text follows.

Glacial Till

The glaciers were large masses of ice that thousands of years ago, originated from snow accumulations to the north. These glaciers flowed southward to the area which is now Hughes County, picking up earth debris as they went. Some of this debris, a mixture of clay, silt, sand, gravel, and boulders was redeposited directly from the ice. Till, the term used to describe this mixture, is also often called "blue clay" or "boulder clay." In the Hughes County area the till is made up of primarily clay and is not considered a source of sand and gravel. However, small isolated sand and gravel hills or lenses may occur within the till.
Glacial Outwash

Glacial outwash is the term used to describe any deposit of glacial debris which has been washed and sorted by water flowing from melting glacier ice. The grain size of these deposits depends upon the velocity of the water which deposited it and the type of material. Deposits left by a slow flowing stream are made up of primarily silts and clays. Rapidly flowing streams may have left streambeds composed entirely of boulders. Most glacial outwash, however, is made up of an assortment of sand and gravel with minor amounts of finer and coarser materials. Deposits of glacial outwash are the major source of sand and gravel in Hughes County.

Alluvium

Alluvium is the term used to describe the material deposited by streams since the retreat of the glaciers. Grain size of the alluvial deposits is determined by the same factors as glacial outwash. Alluvium is found in the valleys of present-day streams and can often be a good source of sand and gravel.

Terrace Deposits

Terrace deposits are flat-topped alluvial or outwash deposits that are remnants of former flood plains. The streams which originally deposited the material have since cut their channels deeper and developed new flood plains at lower levels. Much of the sand and gravel found in Hughes County occurs in this type of deposit.

Bedrock

Bedrock is defined as the older, consolidated rocks that lie beneath the glacial deposits. In Hughes County, the bedrock directly underlying the glacial deposits is Pierre Shale, a gray to black, very clayey material. It is exposed at the surface in many areas along the Missouri River and other stream valleys in Hughes County. The Pierre Shale, which is several hundred feet thick, contains no deposits of sand and gravel.

EXPLANATION OF TABLES

Table 1 is a list of only those test holes in which sand or gravel was encountered in the upper 25 feet. This table gives the location of the test hole, and the depth and description of the sand and gravel deposits. The complete logs of all the test holes drilled in Hughes County are in the files of the South Dakota Geological Survey. The South Dakota Geological Survey, the United States Geological Survey, the South Dakota Division of Water
Table 2 is a list of sand, gravel, and filler pits on file with the South Dakota Division of Highways. This table gives the landowner and location of the pit, the thickness of overburden, the thickness of sand and gravel being mined and the type of aggregate deposit. The actual thickness of a deposit may be greater than that which is listed in the table as being mined.

EXPLANATION OF MAP

The map shows the locations of the test holes and sand and gravel pits. It also shows the towns, major highways, and major lakes, rivers, and creeks.

Test-hole data are shown on the map using three types of symbols. A dot (.) represents a test hole in which sand or gravel was found within 25 feet of the land surface, with less than 5 feet of overburden. A square ([]]) indicates that sand or gravel was found within 25 feet of the land surface but there was greater than 5 feet of overburden. These two types of symbols are numbered and the pertinent test-hole information is listed in table 1. The third symbol is an open circle (○), which indicates that no sand or gravel was found within 25 feet of the land surface. Logs of these test holes are available from the South Dakota Geological Survey. Locations of the sand, gravel, and filler pits are indicated by a crossed pick and shovel (X). The pits which are numbered are listed in table 2, and additional information is on file at the Department of Transportation, Division of Highways, in Pierre. No attempt was made to distinguish the inactive pits from the actively mined pits.

To aid in the delineation of the most promising areas of finding sand and gravel, the map has been divided into three areas of types, "good," "fair," and "poor." These three types of areas were differentiated using test-hole data, sand and gravel pit locations, soil survey information, topographic map and aerial photo interpretation, and field observations. Areas with "good" and "fair" probability of finding sand and gravel have been assigned a letter on the map and are described in the following section.

Sand and gravel deposits found in the "good" areas are generally thick, have very little overburden, and cover a broad area. In these areas, much mining for sand and gravel has already occurred and is occurring at the present time. Sand and gravel deposits found in the "fair" areas are generally thinner, have more overburden, or are laterally discontinuous. There are sand and gravel deposits in the "poor" areas, but a very expensive and exhaustive exploration program would be needed to locate all of these deposits.
Sand and Gravel

Area "A," designated as "good," is a very thick, continuous deposit of sands and gravels. These deposits are terrace deposits formed by the Ancestral Missouri River, an ice-marginal stream valley now occupied by the Missouri River. There is little or no overburden over most of the area. The deposit has a maximum thickness of greater than 100 feet, with an average thickness of about 50 feet for all test holes drilled.

The areas marked "B" and "C" also contain terrace deposits. These areas have been designated as "fair" because they are relatively thin and less continuous. Glacial till and Pierre Shale are found locally at the surface in these areas. Area "C" also represents outwash deposits on the Joe Creek valley floor.

Area "D," designated as "good," is a large terrace deposit of glacial outwash located between Chapelle Creek and South Chapelle Creek. The deposit ranges in thickness from 10 to 24 feet and has an average of about 3 feet of overburden in the test holes drilled.

Area "E" is also a remnant terrace deposit along South Chapelle Creek. It is, however, a very thin deposit and has been designated as "fair."

The areas marked "F," designated as "fair," are found in the Chapelle Creek valley. Although the sand and gravel is very thick in some areas, it remains mostly as discontinuous remnants along the valley walls.

Area "G" is a terrace deposit of the Ancestral Missouri River. The area contains very thick deposits of sand and gravel but has been designated as "fair" because of the large thicknesses of overburden, consisting of silts and clays.

The areas marked "H," designated as "fair," contain remnant terrace deposits of the Ancestral Missouri River. These remnants occur as large hills of sand and gravel between which Pierre Shale can be found exposed at the surface.

Area "I," designated as "good," is a very thick, continuous sand and gravel deposit, which occupies the present-day Missouri River Valley floor. The deposit averages about 60 feet in thickness with little or no overburden.

Area "J," designated as "fair," is located in the valley of Medicine Knoll Creek. It contains remnant outwash deposits along the valley floor and remnant terrace deposits along the valley walls. Very coarse gravels were encountered in the test holes drilled in this area.

Area "K," designated as "fair," contains remnant outwash deposits in the valley of Dry Run. Most of the deposit has been
removed by erosion since the time of glacialiation, leaving small isolated hills of sand and gravel.

Area "L," designated as "fair," occupies a large depression with an outlet to the south. Fine sand is found around the flanks of the area and also at depth within the area. An average of about 15 feet of silty overburden covers the sand where it was found in the test holes drilled.

Area "M," designated as "fair," contains sand and gravel deposits within the South Fork Medicine Knoll Creek valley. The outwash deposits are found as remnants of terraces along the valley walls and in discontinuous deposits along the valley floor.

The areas marked "N" and "O" contain sand and gravel deposits which occupy the Medicine Knoll Creek Valley. Area "N," designated as "good," is a terrace deposit on the eastern wall of the Medicine Knoll Creek valley. The sands and gravels here are up to 35 feet thick, with little overburden. Extensive mining for sand and gravel has occurred in this area. Area "O," designated as "fair," is made up of outwash deposits on the valley floor and remnant terrace deposits along the valley walls of Medicine Knoll Creek and a small unnamed creek which enters the valley from the northwest. The valley floor has been designated as "fair" because of the large amounts of silty, clayey overburden which covers the sand and gravel.

Area "P," designated as "fair," contains remnant outwash deposits in small knobs along an east-west trending ridge. The area also includes remnant terrace deposits along the valley walls of a small unnamed creek which enters Medicine Knoll Creek from the northeast.

The areas marked "Q" and "R" represent outwash deposits within the Spring Creek valley. The areas marked "Q" are designated as "fair" because the sand and gravel deposits are laterally discontinuous or have a large amount of overburden. The areas marked "R" have been designated as "good," because the sand and gravel deposits are thicker (up to 98 feet), cover a broad area and have less overburden (average of about 5 feet).

Area "S" is a terrace of the Ancestral Missouri River. This deposit has up to 76 feet of sand and gravel but has been designated as "fair" because an average of about 15 feet of silty overburden was encountered in the test holes drilled.

**ECONOMIC CONSIDERATIONS**

It should be emphasized that this study is quite general and should be used only as a guide to further exploration and development of the sand and gravel resources. Hughes County contains a large amount of unused sand and gravel. The development of a specific site, however, would depend upon material specifications for the desired use, development costs, transportation costs, and future markets.
### TABLE 1. LIST OF TEST HOLES IN HUGHES COUNTY, SOUTH DAKOTA, WHICH CONTAIN SAND OR GRAVEL IN THE UPPER 25 FEET.

LITHOLOGIC DESCRIPTIONS, AS LISTED, HAVE BEEN CONDENSED FROM DATA CONTAINED IN Logs ON FILE AT THE SOUTH DAKOTA GEOLOGICAL SURVEY OFFICE, VERMILLION, SOUTH DAKOTA, AND CONTAIN ONLY INFORMATION WHICH HAS BEEN DEEMED MOST USEFUL FOR THIS STUDY. NUMERICAL VALUES INDICATE DEPTH IN FEET BELOW LAND SURFACE.

83
Good probability of finding sand or gravel deposits.

Fair probability of finding sand or gravel deposits.

Poor probability of finding sand or gravel deposits.

Letters A through S designate areas described in the text.

Test hole containing sand or gravel within 25 feet of the land surface with 0-5 feet of overburden.

Test hole containing sand or gravel within 25 feet of the land surface with 6-25 feet of overburden.

Test hole containing no sand or gravel within 25 feet of the land surface.

Sand and gravel pits—those with a number are listed in Table 2.
